

Chapter 3: Introduction to SQL

Database System Concepts, 6th Ed.

©Silberschatz, Korth and Sudarshan See <u>www.db-book.com</u> for conditions on re-use

- Overview of The SQL Query Language
- Data Definition
- Basic Query Structure
- Additional Basic Operations
- Set Operations
- Null Values
- Aggregate Functions
- Nested Subqueries
- Modification of the Database

- IBM Sequel language developed as part of System R project at the IBM San Jose Research Laboratory
- Renamed Structured Query Language (SQL)
- ANSI and ISO standard SQL:
 - SQL-86
 - SQL-89
 - SQL-92
 - SQL:1999 (language name became Y2K compliant!)
 - SQL:2003
- Commercial systems offer most, if not all, SQL-92 features, plus varying feature sets from later standards and special proprietary features.
 - Not all examples here may work on your particular system.

Data Definition Language

The SQL data-definition language (DDL) allows the specification of information about relations, including:

- The schema for each relation.
- The domain of values associated with each attribute.
- Integrity constraints
- And as we will see later, also other information such as
 - The set of indices to be maintained for each relations.
 - Security and authorization information for each relation.
 - The physical storage structure of each relation on disk.

Domain Types in SQL

- **char(n).** Fixed length character string, with user-specified length *n*.
- varchar(n). Variable length character strings, with user-specified maximum length n.
- **int.** Integer (a finite subset of the integers that is machine-dependent).
- smallint. Small integer (a machine-dependent subset of the integer domain type).
- numeric(p,d). Fixed point number, with user-specified precision of p digits, with d digits to the right of decimal point. (ex., numeric(3,1), allows 44.5 to be stores exactly, but not 444.5 or 0.32)
- real, double precision. Floating point and double-precision floating point numbers, with machine-dependent precision.
- float(n). Floating point number, with user-specified precision of at least n digits.
- More are covered in Chapter 4.

Create Table Construct

An SQL relation is defined using the **create table** command:

create table $r (A_1 D_1, A_2 D_2, ..., A_n D_n, (integrity-constraint_1),$

(integrity-constraint_k))

- *r* is the name of the relation
- each A_i is an attribute name in the schema of relation r
- D_i is the data type of values in the domain of attribute A_i

Example:

create table *instructor* (*ID* char(5), *name* varchar(20), *dept_name* varchar(20), *salary* numeric(8,2))

Integrity Constraints in Create Table

- not null
- **primary key** $(A_1, ..., A_n)$
- **foreign key** $(A_m, ..., A_n)$ references r

Example:

create table instructor (ID char(5), name varchar(20) not null, dept_name varchar(20), salary numeric(8,2), primary key (ID), foreign key (dept_name) references department);

primary key declaration on an attribute automatically ensures not null

And a Few More Relation Definitions

create table student (

IDvarchar(5),namevarchar(20) not null,dept_namevarchar(20),tot_crednumeric(3,0),primary key (ID),foreign key (dept_name) references department);

create table takes (

ID	varchar(5),
course_id	varchar(8),
sec_id	varchar(8),
semester	varchar(6),
year	numeric (4,0),
grade	varchar(2),
primary key	(ID, course_id, sec_id, semester, year) ,
foreign key	(ID) references student,
foreign key	(course_id, sec_id, semester, year) references section);

 Note: sec_id can be dropped from primary key above, to ensure a student cannot be registered for two sections of the same course in the same semester

And more still

create table course (course_id varchar(8), title varchar(50), dept_name varchar(20), credits numeric(2,0), primary key (course_id), foreign key (dept_name) references department);

Updates to tables

Insert

insert into instructor values ('10211', 'Smith', 'Biology', 66000);

- Delete
 - Remove all tuples from the student relation
 - delete from student
- Drop Table
 - drop table r
- Alter
 - alter table *r* add *A D*
 - where A is the name of the attribute to be added to relation
 r and D is the domain of A.
 - All exiting tuples in the relation are assigned *null* as the value for the new attribute.
 - alter table *r* drop *A*
 - where A is the name of an attribute of relation r
 - Dropping of attributes not supported by many databases.

Database System Concepts - 6th Edition

Basic Query Structure

A typical SQL query has the form:

select $A_1, A_2, ..., A_n$ from $r_1, r_2, ..., r_m$ where *P*

- *A_i* represents an attribute
- r_i represents a relation
- *P* is a predicate.
- The result of an SQL query is a relation.

The select Clause

The **select** clause lists the attributes desired in the result of a query

- corresponds to the projection operation of the relational algebra
- Example: find the names of all instructors:

select name from instructor

- NOTE: SQL names are case insensitive (i.e., you may use upper- or lower-case letters.)
 - E.g., $Name \equiv NAME \equiv name$
 - Some people use upper case wherever we use bold font.

The select Clause (Cont.)

- SQL allows duplicates in relations as well as in query results.
- To force the elimination of duplicates, insert the keyword distinct after select.
- Find the department names of all instructors, and remove duplicates

select distinct dept_name
from instructor

The keyword **all** specifies that duplicates should not be removed.

select all dept_name from instructor

The select Clause (Cont.)

An asterisk in the select clause denotes "all attributes"

select *
from instructor

An attribute can be a literal with no from clause

select '437'

- Results is a table with one column and a single row with value "437"
- Can give the column a name using:

select '437' as FOO

An attribute can be a literal with **from** clause

select 'A' from instructor

 Result is a table with one column and N rows (number of tuples in the instructors table), each row with value "A"

The select Clause (Cont.)

- The select clause can contain arithmetic expressions involving the operation, +, -, *, and /, and operating on constants or attributes of tuples.
 - The query:

select *ID*, *name*, *salary/12* **from** *instructor*

would return a relation that is the same as the *instructor* relation, except that the value of the attribute *salary* is divided by 12.

• Can rename "salary/12" using the **as** clause:

select ID, name, salary/12 as monthly_salary

The where Clause

The **where** clause specifies conditions that the result must satisfy

- Corresponds to the selection predicate of the relational algebra.
- To find all instructors in Comp. Sci. dept

select name
from instructor
where dept_name = 'Comp. Sci.'

Comparison results can be combined using the logical connectives and, or, and not

• To find all instructors in Comp. Sci. dept with salary > 80000

select name
from instructor
where dept_name = Comp. Sci.' and salary > 80000

Comparisons can be applied to results of arithmetic expressions.

The from Clause

The **from** clause lists the relations involved in the query

- Corresponds to the Cartesian product operation of the relational algebra.
- Find the Cartesian product *instructor X teaches*

select *
from instructor, teaches

- generates every possible instructor teaches pair, with all attributes from both relations.
- For common attributes (e.g., *ID*), the attributes in the resulting table are renamed using the relation name (e.g., *instructor.ID*)
- Cartesian product not very useful directly, but useful combined with where-clause condition (selection operation in relational algebra).

Cartesian Product

instructor

teaches

ID	name	dept_n	ame sala	iry	ID	course_i	d sec_	_id sem	ester	year

Database System Concepts - 6th Edition

©Silberschatz, Korth and Sudarshan

Find the names of all instructors who have taught some course and the course_id

select name, course_id
 from instructor , teaches
 where instructor.ID = teaches.ID

Find the names of all instructors in the Art department who have taught some course and the course_id

select name, course_id from instructor, teaches where instructor.ID = teaches.ID and instructor. dept_name = 'Art'

The Rename Operation

The SQL allows renaming relations and attributes using the **as** clause: *old-name* **as** *new-name*

Find the names of all instructors who have a higher salary than some instructor in 'Comp. Sci'.

select distinct *T.name* from *instructor* as *T, instructor* as *S* where *T.salary* > *S.salary* and *S.dept_name* = 'Comp. Sci.'

Keyword **as** is optional and may be omitted *instructor* **as** $T \equiv instructor T$

Self Join Example

Relation emp-super

person	supervisor
Bob	Alice
Mary	Susan
Alice	David
David	Mary

- Find the supervisor of "Bob"
- Find the supervisor of the supervisor of "Bob"
- Find ALL the supervisors (direct and indirect) of "Bob

String Operations

- SQL includes a string-matching operator for comparisons on character strings. The operator **like** uses patterns that are described using two special characters:
 - percent (%). The % character matches any substring.
 - underscore (_). The _ character matches any character.
- Find the names of all instructors whose name includes the substring "dar".

select name from instructor where name like '%dar%'

Match the string "100%"

like '100 \%' escape '\'

in that above we use backslash (\) as the escape character.

String Operations (Cont.)

- Patterns are case sensitive.
- Pattern matching examples:
 - 'Intro%' matches any string beginning with "Intro".
 - '%Comp%' matches any string containing "Comp" as a substring.
 - '___' matches any string of exactly three characters.
 - '___%' matches any string of at least three characters.
- SQL supports a variety of string operations such as
 - concatenation (using "II")
 - converting from upper to lower case (and vice versa)
 - finding string length, extracting substrings, etc.

Ordering the Display of Tuples

List in alphabetic order the names of all instructors

select distinct name from instructor order by name

- We may specify desc for descending order or asc for ascending order, for each attribute; ascending order is the default.
 - Example: order by name desc
- Can sort on multiple attributes
 - Example: order by dept_name, name

Predicates in the where Clause

- SQL includes a **between** comparison operator
- Example: Find the names of all instructors with salary between \$90,000 and \$100,000 (that is, \geq \$90,000 and \leq \$100,000)
 - select name
 from instructor
 where salary between 90000 and 100000
- Tuple comparison
 - select name, course_id
 from instructor, teaches
 where (instructor.ID, dept_name) = (teaches.ID, 'Biology');

Duplicates

- In relations with duplicates, SQL can define how many copies of tuples appear in the result.
- Multiset versions of some of the relational algebra operators given multiset relations r₁ and r₂:
 - 1. $\sigma_{\theta}(r_1)$: If there are c_1 copies of tuple t_1 in r_1 , and t_1 satisfies selections σ_{θ} , then there are c_1 copies of t_1 in $\sigma_{\theta}(r_1)$.
 - 2. $\Pi_A(\mathbf{r})$: For each copy of tuple t_1 in r_1 , there is a copy of tuple $\Pi_A(t_1)$ in $\Pi_A(r_1)$ where $\Pi_A(t_1)$ denotes the projection of the single tuple t_1 .
 - 3. $r_1 \ge r_2$: If there are c_1 copies of tuple t_1 in r_1 and c_2 copies of tuple t_2 in r_2 , there are $c_1 \ge c_2$ copies of the tuple t_1 . t_2 in $r_1 \ge r_2$

Duplicates (Cont.)

Example: Suppose multiset relations *r*₁ (*A*, *B*) and *r*₂ (*C*) are as follows:

 $r_1 = \{(1, a) (2, a)\} \qquad r_2 = \{(2), (3), (3)\}$

Then $\Pi_B(r_1)$ would be {(a), (a)}, while $\Pi_B(r_1) \ge r_2$ would be

 $\{(a,2), (a,2), (a,3), (a,3), (a,3), (a,3)\}$

SQL duplicate semantics:

select $A_{1,,} A_{2}, ..., A_{n}$ from $r_{1}, r_{2}, ..., r_{m}$ where *P*

is equivalent to the *multiset* version of the expression:

$$\prod_{A_1,A_2,\ldots,A_n} (\sigma_P(r_1 \times r_2 \times \ldots \times r_m))$$

Set Operations

Find courses that ran in Fall 2009 or in Spring 2010

(select course_id from section where sem = 'Fall' and year = 2009)
union
(select course_id from section where sem = 'Spring' and year = 2010)

Find courses that ran in Fall 2009 and in Spring 2010

(select course_id from section where sem = 'Fall' and year = 2009)
intersect
(select course_id from section where sem = 'Spring' and year = 2010)

Find courses that ran in Fall 2009 but not in Spring 2010

(select course_id from section where sem = 'Fall' and year = 2009)
except
(select course_id from section where sem = 'Spring' and year = 2010)

Set Operations (Cont.)

Find the salaries of all instructors that are less than the largest salary.

- select distinct *T.salary* from instructor as *T*, instructor as *S* where *T.salary* < *S.salary*
- Find all the salaries of all instructors
 - select distinct salary
 from instructor
- Find the largest salary of all instructors.
 - (select "second query")
 except (select "first query")

Set Operations (Cont.)

- Set operations union, intersect, and except
 - Each of the above operations automatically eliminates duplicates
- To retain all duplicates use the corresponding multiset versions union all, intersect all and except all.
- Suppose a tuple occurs *m* times in *r* and *n* times in *s*, then, it occurs:
 - m + n times in r union all s
 - min(*m*,*n*) times in *r* intersect all *s*
 - max(0, m n) times in r except all s

Null Values

- It is possible for tuples to have a null value, denoted by *null*, for some of their attributes
 - *null* signifies an unknown value or that a value does not exist.
- The result of any arithmetic expression involving *null* is *null*
 - Example: 5 + *null* returns null
- The predicate is null can be used to check for null values.
 - Example: Find all instructors whose salary is null.

select name from instructor where salary is null

Null Values and Three Valued Logic

- Three values *true*, *false*, *unknown*
- Any comparison with *null* returns *unknown*
 - Example: 5 < null or null <> null or null = null
 - Three-valued logic using the value *unknown*:
 - OR: (unknown or true) = true, (unknown or false) = unknown (unknown or unknown) = unknown
 - AND: (true and unknown) = unknown, (false and unknown) = false, (unknown and unknown) = unknown
 - NOT: (not unknown) = unknown
 - "*P* is unknown" evaluates to true if predicate *P* evaluates to unknown
- Result of where clause predicate is treated as *false* if it evaluates to unknown

Aggregate Functions

These functions operate on the multiset of values of a column of a relation, and return a value

avg: average valuemin: minimum valuemax: maximum valuesum: sum of valuescount: number of values

Aggregate Functions (Cont.)

- Find the average salary of instructors in the Computer Science department
 - select avg (salary)
 from instructor
 where dept_name= 'Comp. Sci.';
- Find the total number of instructors who teach a course in the Spring 2010 semester
 - select count (distinct *ID*)
 from *teaches* where *semester* = 'Spring' and *year* = 2010;
- Find the number of tuples in the *course* relation
 - select count (*) from course;

Aggregate Functions – Group By

- Find the average salary of instructors in each department
 - select dept_name, avg (salary) as avg_salary from instructor group by dept_name;

ID	name	dept_name	salary
76766	Crick	Biology	72000
45565	Katz	Comp. Sci.	75000
10101	Srinivasan	Comp. Sci.	65000
83821	Brandt	Comp. Sci.	92000
98345	Kim	Elec. Eng.	80000
12121	Wu	Finance	90000
76543	Singh	Finance	80000
32343	El Said	History	60000
58583	Califieri	History	62000
15151	Mozart	Music	40000
33456	Gold	Physics	87000
22222	Einstein	Physics	95000

dept_name	avg_salary
Biology	72000
Comp. Sci.	77333
Elec. Eng.	80000
Finance	85000
History	61000
Music	40000
Physics	91000

Aggregation (Cont.)

Attributes in **select** clause outside of aggregate functions must appear in **group by** list

 /* erroneous query */ select dept_name, ID, avg (salary) from instructor group by dept_name;

Aggregate Functions – Having Clause

Find the names and average salaries of all departments whose average salary is greater than 42000

select dept_name, avg (salary)
from instructor
group by dept_name
having avg (salary) > 42000;

Note: predicates in the **having** clause are applied after the formation of groups whereas predicates in the **where** clause are applied before forming groups

Null Values and Aggregates

Total all salaries

select sum (salary)
from instructor

- Above statement ignores null amounts
- Result is *null* if there is no non-null amount
- All aggregate operations except count(*) ignore tuples with null values on the aggregated attributes
- What if collection has only null values?
 - count returns 0
 - all other aggregates return null

Nested Subqueries

- SQL provides a mechanism for the nesting of subqueries. A subquery is a select-from-where expression that is nested within another query.
- The nesting can be done in the following SQL query

select $A_1, A_2, ..., A_n$ **from** $r_1, r_2, ..., r_m$ **where** *P*

as follows:

- A_i can be replaced be a subquery that generates a single value.
- r_i can be replaced by any valid subquery
- *P* can be replaced with an expression of the form:

B <operation> (subquery)

Where *B* is an attribute and <operation> to be defined later.

Subqueries in the where Clause

A common use of subqueries is to perform tests:

- For set membership
- For set comparisons
- For set cardinality.

Set Membership

Find courses offered in Fall 2009 and in Spring 2010

select distinct course_id
from section
where semester = 'Fall' and year= 2009 and
 course_id in (select course_id
 from section
 where semester = 'Spring' and year= 2010);

Find courses offered in Fall 2009 but not in Spring 2010

Set Membership (Cont.)

Find the total number of (distinct) students who have taken course sections taught by the instructor with *ID* 10101

select count (distinct ID)
from takes
where (course_id, sec_id, semester, year) in
 (select course_id, sec_id, semester, year
 from teaches
 where teaches.ID= 10101);

Note: Above query can be written in a much simpler manner. The formulation above is simply to illustrate SQL features.

Set Comparison – "some" Clause

Find names of instructors with salary greater than that of some (at least one) instructor in the Biology department.

select distinct T.name
from instructor as T, instructor as S
where T.salary > S.salary and S.dept name = 'Biology';

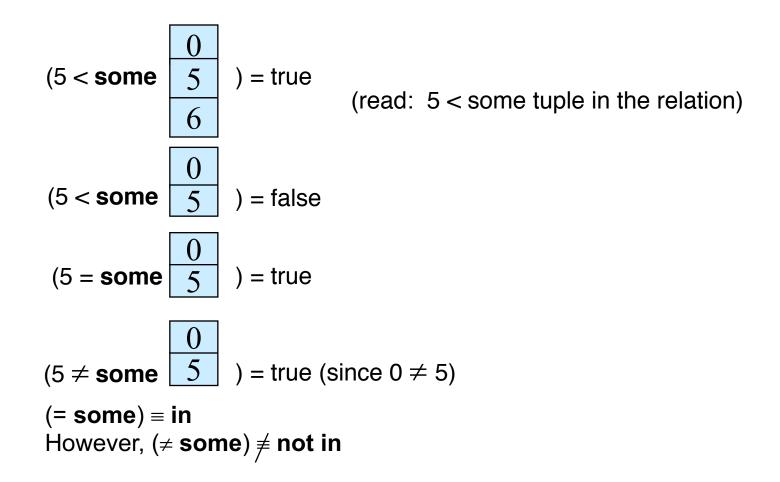

Same query using > some clause

select name from instructor where salary > some (select salary from instructor where dept name = 'Biology');

Definition of "some" Clause

F <comp> some $r \Leftrightarrow \exists t \in r$ such that (F <comp> t) Where <comp> can be: <, \leq , >, =, \neq

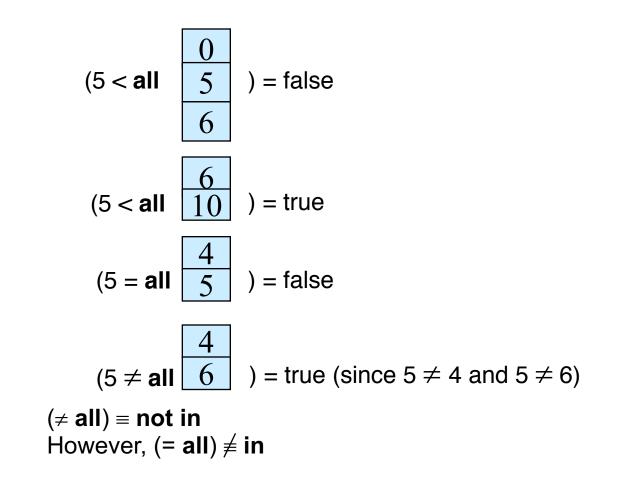

Set Comparison – "all" Clause

Find the names of all instructors whose salary is greater than the salary of all instructors in the Biology department.

Definition of "all" Clause

 $\mathsf{F} < \mathsf{comp} > \mathsf{all} \ r \Leftrightarrow \forall \ t \in r \ (\mathsf{F} < \mathsf{comp} > t)$

Database System Concepts - 6th Edition

Test for Empty Relations

- The exists construct returns the value true if the argument subquery is nonempty.
- exists $r \Leftrightarrow r \neq \emptyset$
- **not exists** $r \Leftrightarrow r = \emptyset$

Use of "exists" Clause

Yet another way of specifying the query "Find all courses taught in both the Fall 2009 semester and in the Spring 2010 semester"

select course_id
from section as S
where semester = 'Fall' and year = 2009 and
 exists (select *
 from section as T
 where semester = 'Spring' and year= 2010
 and S.course_id = T.course_id);

Correlation name – variable S in the outer query

Correlated subquery – the inner query

Use of "not exists" Clause

Find all students who have taken all courses offered in the Biology department.

- · First nested query lists all courses offered in Biology
- Second nested query lists all courses a particular student took
- Note that $X Y = \emptyset \iff X \subseteq Y$

Note: Cannot write this query using = **all** and its variants

Test for Absence of Duplicate Tuples

- The unique construct tests whether a subquery has any duplicate tuples in its result.
- The unique construct evaluates to "true" if a given subquery contains no duplicates.
- Find all courses that were offered at most once in 2009

Subqueries in the from Clause

SQL allows a subquery expression to be used in the **from** clause

Find the average instructors' salaries of those departments where the average salary is greater than \$42,000."

select dept_name, avg_salary
from (select dept_name, avg (salary) as avg_salary
 from instructor
 group by dept_name)
where avg_salary > 42000;

- Note that we do not need to use the having clause
- Another way to write above query

select dept_name, avg_salary
from (select dept_name, avg (salary)
 from instructor
 group by dept_name) as dept_avg (dept_name, avg_salary)
where avg_salary > 42000;

The with Clause

- The with clause provides a way of defining a temporary relation whose definition is available only to the query in which the with clause occurs.
- Find all departments with the maximum budget

with max_budget (value) as
 (select max(budget)
 from department)
select department.name
from department, max_budget
where department.budget = max_budget.value;

Complex Queries using the with Clause

Find all departments where the total salary is greater than the average of the total salary at all departments

with dept_total (dept_name, value) as
 (select dept_name, sum(salary)
 from instructor
 group by dept_name),
 dept_total_avg(value) as
 (select avg(value)
 from dept_total)
select dept_name
from dept_total, dept_total_avg
where dept_total.value > dept_total_avg.value;

Subqueries in the select Clause: Scalar Subquery

- Scalar subquery is one which is used where a single value is expected
- List all departments along with the number of instructors in each department

select dept_name, (select count(*) from instructor where department.dept_name = instructor.dept_name) as num_instructors from department;

Runtime error if subquery returns more than one result tuple

Modification of the Database

- Deletion of tuples from a given relation.
- Insertion of new tuples into a given relation
- Updating of values in some tuples in a given relation

Delete all instructors

delete from instructor

Delete all instructors from the Finance department delete from instructor where dept_name= 'Finance';

Delete all tuples in the *instructor* relation for those instructors associated with a department located in the Watson building.

delete from *instructor* where *dept name* in (select *dept name* from *department* where *building* = 'Watson');

Deletion (Cont.)

Delete all instructors whose salary is less than the average salary of instructors

- Problem: as we delete tuples from deposit, the average salary changes
- Solution used in SQL:
 - 1. First, compute **avg** (salary) and find all tuples to delete
 - Next, delete all tuples found above (without recomputing avg or retesting the tuples)

Insertion

Add a new tuple to *course*

insert into *course* values ('CS-437', 'Database Systems', 'Comp. Sci.', 4);

or equivalently

insert into course (course_id, title, dept_name, credits)
values ('CS-437', 'Database Systems', 'Comp. Sci.', 4);

Add a new tuple to student with tot_creds set to null insert into student values ('3003', 'Green', 'Finance', null);

Insertion (Cont.)

Add all instructors to the *student* relation with tot_creds set to 0

insert into student select ID, name, dept_name, 0 from instructor

The select from where statement is evaluated fully before any of its results are inserted into the relation.

Otherwise queries like

insert into table1 select * from table1

would cause problem

Increase salaries of instructors whose salary is over \$100,000 by 3%, and all others by a 5%

• Write two **update** statements:

update instructor set salary = salary * 1.03 where salary > 100000; update instructor set salary = salary * 1.05 where salary <= 100000;

The order is important

• Can be done better using the **case** statement (next slide)

Case Statement for Conditional Updates

Same query as before but with case statement

```
update instructor
set salary = case
when salary <= 100000 then salary * 1.05
else salary * 1.03
end
```

Updates with Scalar Subqueries

Recompute and update tot_creds value for all students update student S set tot_cred = (select sum(credits) from takes, course where takes.course_id = course.course_id and S.ID= takes.ID.and takes.grade <> 'F' and takes.grade is not null);

Sets *tot_creds* to null for students who have not taken any course
Instead of **sum**(*credits*), use:

case when sum(credits) is not null then sum(credits) else 0 end

End of Chapter 3

Database System Concepts, 6th Ed.

©Silberschatz, Korth and Sudarshan See <u>www.db-book.com</u> for conditions on re-use
